Unbiased Implicit Variational Inference

Michalis K. Titsias & Francisco J. R. Ruiz

December 17th, 2018

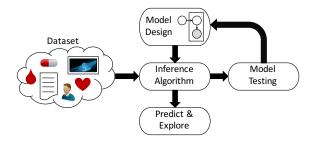

Probabilistic Modeling Pipeline

- Posit generative process with hidden and observed variables
- Given the data, reverse the process to infer hidden variables
- Use hidden structure to make predictions, explore the dataset, etc.

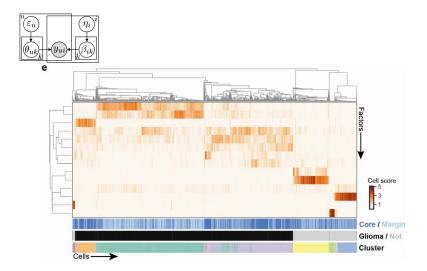

Probabilistic Modeling Pipeline

- Incorporate domain knowledge with interpretable components
- Separate assumptions from computation
- Facilitate collaboration with domain experts

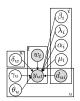

Applications: Gene Signature Discovery

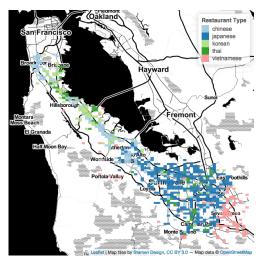

Can we identify de novo gene expression patterns in scRNA-seq?

Applications: Consumer Preferences

Can we use mobile location data to find the most promising location for a new restaurant?

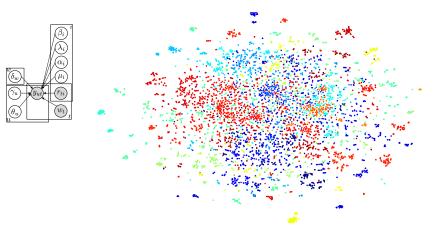

Restaurants in the Bay Area

Applications: Shopping Behavior

Can we use past shopping transactions to learn customer preferences and predict demand as a function of price?

Background: Probabilistic Modeling

Latent variables z

- Observations x
- ▶ Probabilistic model p(x, z)

• Posterior
$$p(z | x) = \frac{p(x,z)}{\int p(x,z)dz}$$

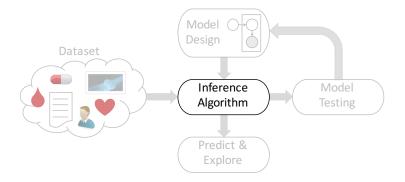

Background: Probabilistic Modeling

$$p(z \mid x) = \frac{p(x, z)}{\int p(x, z) dz}$$

> The posterior allows us to explore the data and make predictions

 Approximating the posterior is the central challenge of Bayesian inference

Inference

Background: Variational Inference

Variational inference approximates the posterior

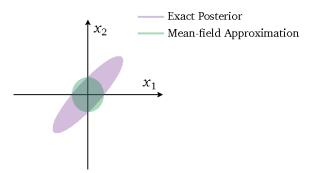

- Find simpler distribution $q_{\theta}(z) \approx p(z | x)$
- ▶ Use KL divergence to measure similarity between $q_{\theta}(z)$ and p(z | x)
- Minimize KL divergence w.r.t. variational parameters θ

Background: Mean-Field Variational Inference

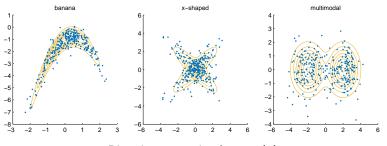

Classical VI: Mean-field variational distribution:

$$q_{\theta}(z) = \prod_{n} q_{\theta_{n}}(z_{n})$$

Simple, but might not be accurate

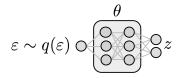

Our Goal: More Expressive Variational Distributions

Blue dots: samples from $q_{\theta}(z)$

Variational Inference with Implicit Distributions

• Easy to draw samples from $q_{\theta}(z)$:

sample
$$\varepsilon \sim q(\varepsilon)$$
; set $z = f_{\theta}(\varepsilon)$

• Cannot evaluate the density $q_{\theta}(z)$

Flexible distribution due to the non-linear transformation

VI with Implicit Distributions is Hard

The VI objective is the ELBO (equivalent to minimizing KL),

$$\mathcal{L}(\theta) = \mathbb{E}_{q_{\theta}(z)} \left[\underbrace{\log p(x, z)}_{\text{model}} - \underbrace{\log q_{\theta}(z)}_{\text{entropy}} \right]$$

• Gradient of the objective $\nabla_{\theta} \mathcal{L}(\theta)$ (reparameterization)

$$\nabla_{\theta} \mathcal{L}(\theta) = \mathbb{E}_{q(\varepsilon)} \Big[\nabla_{z} \left(\log p(x, z) - \log q_{\theta}(z) \right) \Big|_{z = f_{\theta}(\varepsilon)} \times \nabla_{\theta} f_{\theta}(\varepsilon) \Big]$$

• Monte Carlo estimates require $\nabla_z \log q_\theta(z)$ (not available)

Unbiased Implicit Variational Inference

▶ We describe how to obtain an unbiased Monte Carlo estimator

- We avoid density ratio estimation
- ► Key ideas:
 - 1. Semi-implicit construction of $q_{\theta}(z)$
 - 2. Gradient of the entropy component as an expectation,

 $\nabla_z \log q_\theta(z) = \mathbb{E}_{\operatorname{distrib}(\cdot)} [\operatorname{function}(z, \cdot)]$

Implicit distribution:

$$\varepsilon \sim q(\varepsilon) \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc 0$$

(Semi-)implicit distribution:

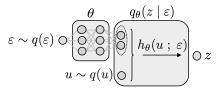

(Semi-)implicit distribution

$$\varepsilon \sim q(\varepsilon) \bigcirc \bigcup_{u \sim q(u)}^{\theta} \bigcup_{i=1}^{q_{\theta}(z \mid \varepsilon)} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \sim q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow i \to q(u) \bigcup_{i=1}^{d} h_{\theta}(u ; \varepsilon) \\ \downarrow$$

Example: The conditional $q_{\theta}(z | \varepsilon)$ is a Gaussian,

$$q_{ heta}(z \,|\, arepsilon) = \mathcal{N}\left(z \,|\, \mu_{ heta}(arepsilon), \Sigma_{ heta}(arepsilon)
ight)$$

(Semi-)implicit distribution

• The distribution $q_{\theta}(z)$ is still **implicit**,

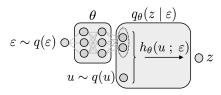

Easy to sample,

sample
$$\varepsilon \sim q(\varepsilon)$$
,
obtain $\mu_{\theta}(\varepsilon)$ and $\Sigma_{\theta}(\varepsilon)$
sample $z \sim \mathcal{N}(z \mid \mu_{\theta}(\varepsilon), \Sigma_{\theta}(\varepsilon))$

• The variational distribution $q_{\theta}(z)$ is not tractable,

$$q_{ heta}(z) = \int q(arepsilon) q_{ heta}(z \,|\, arepsilon) darepsilon$$

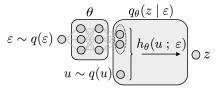

▶ (Semi-)implicit distribution

• Assumptions on the conditional $q_{\theta}(z | \varepsilon)$:

- Reparameterizable
- Tractable gradient ∇_z log q_θ(z | ε) Note: this is different from ∇_z log q_θ(z) (still intractable)

(Semi-)implicit distribution

► The Gaussian meets both assumptions:

Reparameterizable,

$$u \sim \mathcal{N}(u \mid 0, I), \qquad z = h_{\theta}(u; \varepsilon) = \mu_{\theta}(\varepsilon) + \Sigma_{\theta}(\varepsilon)^{1/2} u$$

Tractable gradient,

$$abla_z \log q_ heta(z\,|\,arepsilon) = - \Sigma_ heta(arepsilon)^{-1}(z-\mu_ heta(arepsilon))$$

UIVI Step 2: Gradient as Expectation

• Goal: Estimate the gradient of the entropy component, $\nabla_z \log q_\theta(z)$

$$\nabla_{z} \log q_{\theta}(z) = \mathbb{E}_{q_{\theta}(\varepsilon' \mid z)} \left[\nabla_{z} \log q_{\theta}(z \mid \varepsilon') \right]$$

Form Monte Carlo estimate,

$$\nabla_{z} \log q_{\theta}(z) \approx \nabla_{z} \log q_{\theta}(z \,|\, \varepsilon'), \qquad \varepsilon' \sim q_{\theta}(\varepsilon' \,|\, z)$$

UIVI: Full Algorithm

The gradient of the ELBO is

$$\nabla_{\theta} \mathcal{L}(\theta) = \mathbb{E}_{q(\varepsilon)q(u)} \Big[\nabla_{z} \left(\log p(x, z) - \log q_{\theta}(z) \right) \Big|_{z = h_{\theta}(u; \varepsilon)} \times \nabla_{\theta} h_{\theta}(u; \varepsilon) \Big]$$

Estimate the gradient based on samples:

1. Sample $\varepsilon \sim q(\varepsilon)$, $u \sim q(u)$ (standard Gaussians)

2. Set
$$z = h_{\theta}(\varepsilon; u) = \mu_{\theta}(\varepsilon) + \Sigma_{\theta}(\varepsilon)^{1/2} u$$

- 3. Evaluate $\nabla_z \log p(x, z)$ and $\nabla_\theta h_\theta(u; \varepsilon)$
- 4. Sample $\varepsilon' \sim q_{\theta}(\varepsilon' \mid z)$
- 5. Approximate $\nabla_z \log q_\theta(z) \approx \nabla_z \log q_\theta(z \mid \varepsilon')$

UIVI: The Reverse Conditional

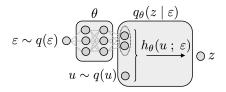

The distribution q_θ(ε' | z) is the reverse conditional The conditional is q_θ(z | ε)

Sample from $q_{\theta}(\varepsilon' | z)$ using HMC, targeting

 $q(arepsilon'\,|\,z) \propto q(arepsilon')q_ heta(z\,|\,arepsilon')$

Problem: HMC is slow... How to accelerate this?

UIVI: The Reverse Conditional

Recall the UIVI algorithm,

- 1. Sample $\varepsilon \sim q(\varepsilon)$, $u \sim q(u)$ (standard Gaussians)
- 2. Set $z = h_{\theta}(\varepsilon; u) = \mu_{\theta}(\varepsilon) + \Sigma_{\theta}(\varepsilon)^{1/2} u$
- 3. Evaluate $\nabla_z \log p(x, z)$ and $\nabla_\theta h_\theta(u; \varepsilon)$
- 4. Sample $\varepsilon' \sim q_{\theta}(\varepsilon' \mid z)$
- 5. Approximate $\nabla_z \log q_\theta(z) \approx \nabla_z \log q_\theta(z \mid \varepsilon')$
- ► We have that $(\varepsilon, z) \sim q_{\theta}(\varepsilon, z) = q(\varepsilon)q_{\theta}(z \,|\, \varepsilon) = q_{\theta}(z)q_{\theta}(\varepsilon \,|\, z)$
- Thus, ε is a sample from $q_{\theta}(\varepsilon \mid z)$
- ▶ To accelerate sampling $\varepsilon' \sim q(\varepsilon' | z)$, initialize HMC at ε

UIVI: The Reverse Conditional

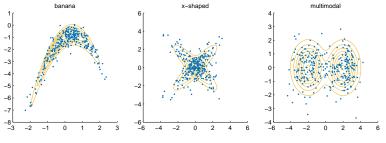

Sample from $q_{\theta}(\varepsilon' | z)$ using HMC targeting

 $q(arepsilon'\,|\,z) \propto q(arepsilon')q_ heta(z\,|\,arepsilon')$

• Initialize HMC at stationarity (using ε)

 \blacktriangleright A few HMC iterations to reduce correlation between ε and ε'

Toy Experiments

Blue dots: samples from $q_{\theta}(z)$

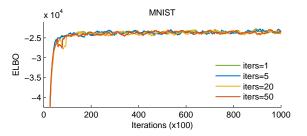

Experiments: Multinomial Logistic Regression

UIVI provides better ELBO and predictive performance than SIVI

Experiments: Multinomial Logistic Regression

$$p(x,z) = p(z) \prod_{n=1}^{N} \frac{\exp\{x_n^{\top} z_{y_n} + z_{0y_n}\}}{\sum_k \exp\{x_n^{\top} z_k + z_{0k}\}}$$

Number of HMC iterations does not significantly impact results

Experiments: VAE

- Model is $p_{\phi}(x, z) = \prod_{n} p(z_n) p_{\phi}(x_n | z_n)$
- Amortized variational distrib. $q_{\theta}(z_n | x_n) = \int q(\varepsilon_n) q_{\theta}(z_n | \varepsilon_n, x_n) d\varepsilon_n$
- Goal: Find model parameters ϕ and variational parameters θ

	average test log-likelihood	
method	MNIST	Fashion-MNIST
Explicit (standard VAE)	-98.29	-126.73
SIVI	-97.77	-121.53
UIVI [this paper]	-94.09	-110.72

UIVI provides better ELBO and predictive performance

Conclusion

- UIVI approximates the posterior with an expressive variational distribution
- The variational distribution is implicit
- UIVI directly optimizes the ELBO
- Good results on Bayesian multinomial logistic regression and VAEs

Proof of the Key Equation

Goal: Prove that

$$\nabla_{z} \log q_{\theta}(z) = \mathbb{E}_{q_{\theta}(\varepsilon \mid z)} \left[\nabla_{z} \log q_{\theta}(z \mid \varepsilon) \right]$$

Start with log-derivative identity,

$$abla_z \log q_ heta(z) = rac{1}{q_ heta(z)}
abla_z q_ heta(z)$$

• Apply the definition of $q_{\theta}(z)$ through a mixture,

$$abla_z \log q_ heta(z) = rac{1}{q_ heta(z)} \int
abla_z q_ heta(z \,|\, arepsilon) q(arepsilon) darepsilon$$

• Apply the log-derivative identity on $q_{\theta}(z \mid \varepsilon)$,

$$abla_z \log q_ heta(z) = rac{1}{q_ heta(z)} \int q_ heta(z \,|\, arepsilon) q_arepsilon(arepsilon)
abla_z \log q_ heta(z \,|\, arepsilon) darepsilon.$$

Apply Bayes' theorem

SIVI

SIVI optimizes a lower bound of the ELBO,

$$\mathcal{L}_{\mathrm{SIVI}}^{(L)}(\theta) = \mathbb{E}_{\varepsilon \sim q(\varepsilon)} \left[\mathbb{E}_{z \sim q_{\theta}(z \mid \varepsilon)} \left[\mathbb{E}_{\varepsilon^{(1)}, \dots, \varepsilon^{(L)} \sim q(\varepsilon)} \left[\log p(x, z) - \log \left(\frac{1}{L+1} \left(q_{\theta}(z \mid \varepsilon) + \sum_{\ell=1}^{L} q_{\theta}(z \mid \varepsilon^{(\ell)}) \right) \right) \right] \right] \right]$$
